What are generative adversarial networks (GANs)?

Generative adversarial networks (GANs) are an innovation in machine learning which uses adversarial training to pit two deep learning algorithms against one another. The goal of a GAN is to create new, synthetic data that is indistinguishable from the real, sample data. The model architecture of a GAN consists of a generator network and a discriminator network. Generators generate new, synthetic data, while discriminators evaluate this new data for authenticity against the real, sample data.

Deepfakes and Synthetic Media

Deepfakes are created through generative adversarial networks. GANs are best utilized for re-creating static photos, but can also generate audio, text, drawings, handwritten notes, video, etc.

Recent advancements in GAN technology have led to re-created videos impersonating various individuals as well as filters on video conferencing platforms that allow impersonation in real time. Although these videos are not 100% foolproof, it can be difficult for average Internet users to tell the difference between deepfakes and real content.

GANs were developed for several positive uses such as Internet content moderation, health data and image recognition, short term weather disaster prevention, and much more. However, this technology has proven to be easily weaponized for malicious causes.

Malicious Use of Deepfakes

As the amount of fake accounts on social media decreases from heights during the 2016 and 2020 elections, malicious actors are improving their usage of deepfakes to manipulate public opinion.

In particular, Russia’s motive isn’t necessarily to get disinformation to trend virally or through conventional news, but instead takes a rather simple approach by infiltrating our news sources. Russia’s “Peace Data Operation,” for example, created 13 well-groomed accounts using stolen identities tied to specific bank and Bitcoin accounts. Spoofs such as these, despite having many mistakes, lead to real risks and manipulation of public opinion.
GANs, Deepfakes, & Synthetic Media

Malicious Use of Deepfakes (Continued)

Well-resourced states will be able to carry out these steps, but opportunities for counter-moves have also emerged. The more nations act, the more visible their patterns and behaviors are. The more we can learn about the technologies, the more we can deal with their repercussions.

Overall, however, most malicious use of deepfakes are against women in the form of deepfake pornography.

Actionable Ideas

Policymakers must utilize legislative measures to first stamp out deepfake pornography, the largest use of deepfake technology. Policymakers should also authorize programs allowing users to install plug-ins in browsers to detect manipulated images.

Combatting deepfake technology and giving law enforcement the tools to crackdown on it will create the technology necessary to address prospective national security threats. The same technology used to create this problem can be used as a solution to defend against security threats and build resiliency.
